CIRCUIT FUNCTION DIAGRAM

SERVICE ALIGNMENT PROCEDURE

PLL microprocessor circuit

Equipment Required

1. Stabilized power supply (DC 14V)
2. Frequency counter with more than 7 digits

Adjustment in crystal oscillator frequency

- (a) Connect the input of frequency counter to TP8. Place the band changeover switch of the receiver in AM position and set receiving frequency to 1404kHz.
- (b) Align trimmer capacitor C903 to have the indication of frequency counter be of 1854000Hz. Refer to Fig. 1.

Note: If receiving frequency of the receiver is not 1404kHz, let the receiving frequency be added by 450kHz, by performing the alignment of C903 (Trimmer capacitor). Correctly perform the alignment; otherwise radio and clock will be affected.

AM circuit

Equipment required

1. AC V.T.V.M.
2. Stabilized power supply (DC 14V)
3. Sweep generator (450kHz)
4. AM RF S.S.G.
5. DC voltage meter ($Z_i \geq 100k\ \Omega$)

(A) AM IF alignment

- (a) Connect the output of the sweep generator to TP1 or antenna receptacle, and the vertical input of the oscilloscope to TP2.

Let the vertical input of the oscilloscope and output of the sweep generator be AC coupled (Refer to Fig. 3).

- (b) Adjust the center frequency of the sweep generator to 450kHz.

- (c) When the waveform of the oscilloscope (Fig. 4) is confirmed, heighten the input sensitivity of oscilloscope as possible, and lower the output of sweep generator. (At this moment, if the waveform seems to be under the influence of external radio wave, change the receiving frequency of the receiver until the influence is minimized. And then perform IF adjustment).

- (d) While viewing the waveform on the oscilloscope, align F701 and F702. Alignment is to be carried out until a maximum and symmetrical waveform is obtained and shown on the scope, where the sharpness of the waveform should not be too high.

Frequency Counter

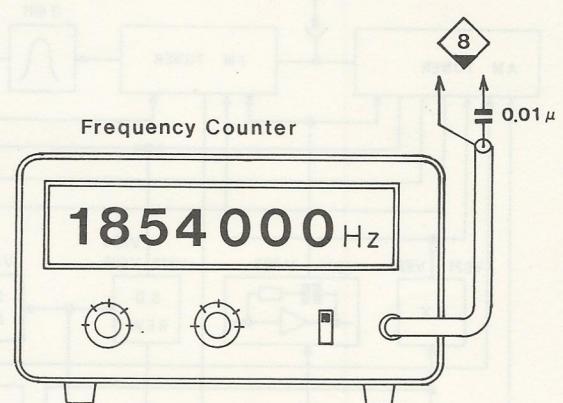

Fig. 1

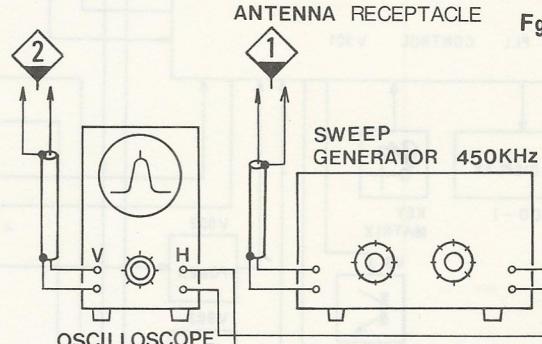

Fig. 2

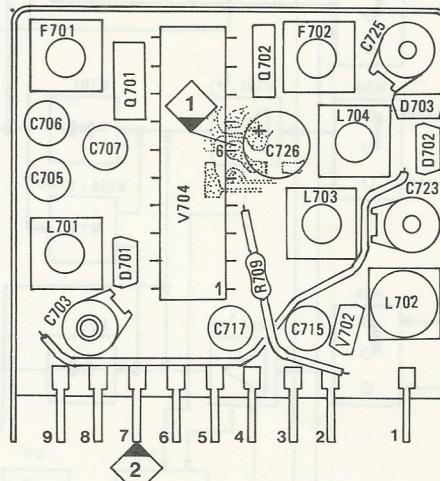

Fig. 3

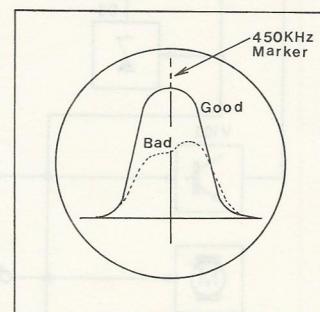

Fig. 4

(B) AM RF (Tracking) alignment

- Connect the V.T.V.M. to the speaker output of either channel, and the output of AM RF S.S.G. to the antenna through dummy antenna (Fig. 5).
- Tuning voltage calibration
Connect DC voltage meter to 9 pin of AM board. Read the indications of DC voltage meter at the lower limit (522kHz) and upper limit (1629kHz). Confirm that the voltage values (lower limit and upper limit) are approximately 1.5V and 7V, respectively. If the values obtained are greatly deviated from the standard ones, adjust L701 and C703.
- Set the frequency of S.G. to 603kHz exactly. Let the output level be the level of AGC being not working (less than $30\mu\text{V}$).
- Align L703 (ANT coil) and L704 (RF coil) to obtain the maximum output. At this moment, the core positions of L703 and L704 should be memorized.
- Set the frequency of S.G. to 1404kHz, and the tuning of the receiver to 1404kHz also. Move C723 and C725 to observe the direction in which the output becomes great.
- Repeat the above mentioned procedure several times. (Ensure that quieting sensitivity is within the specification).

Note:

- If L703 and L704 are shifted slightly, align L704 to obtain the maximum sensitivity. And at this moment, ensure that the upper limit and lower limit of tuning voltage should be in the range of 1V-8.5V.
- Since D701, D702 and D703 are used as a single set, these three components should be replaced at the same time even if only one of the three is defective.

(C) AM stop signal circuit alignment

Note: In the case of AM, confirmation is made by only performing the alignment of IF and RF.

- Connect the output of AM RF signal generator to the antenna, set the frequency of signal generator to 999kHz exactly, perform auto search, change the output level of signal generator, and then confirm whether search stop is conducted correctly or not.

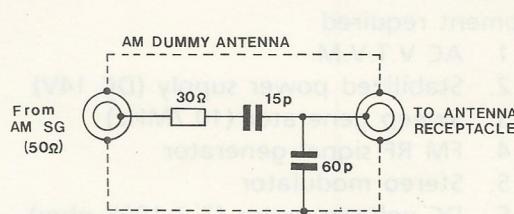

Fig. 5

FM circuit

Equipment required

1. AC V.T.V.M.
2. Stabilized power supply (DC 14V)
3. Sweep generator (10.7MHz)
4. FM RF signal generator
5. Stereo modulator
6. DC voltage meter ($Z_i \geq 100k\text{ ohm}$)

(A) FM IF alignment

- (a) Connect the output of sweep generator to the antenna, and the vertical input of oscilloscope to the TP6. (Refer to Fig. 6)
- (b) Set the center frequency of sweep generator to 10.7MHz.

Note: Heighten the input sensitivity of oscilloscope as much as possible. The output level of sweep generator should be set at the level at which the limiter of IF amplifier can not be working.

- (c) Align F601 in order that the waveform of the oscilloscope may be the same as that shown in Fig. 7. The amplitude of the waveform should be maximum and symmetrical with respect to the vertical axis, and the end portion should be round shaped.
- (d) Place C.R circuit in Fig. 8 to the vertical input of oscilloscope, and connect the input to TP6. At this moment, the input sensitivity of oscilloscope is lower than that in procedure (b), and the output level of sweep generator will lower further.
- (e) Align F621 to have the waveform shown on the oscilloscope be the same as that shown in Fig. 9.
- (f) Connect the output of FM RF signal generator to the antenna through dummy antenna. Set the frequency of FM RF sweep generator to 98.1MHz exactly, and tune the receiver to 98.1MHz as well. Let the output level of FM RF sweep generator be 1mv. Refer to Fig. 10.
- (g) Connect DC voltage meter to TP3 and TP4. The voltage range of the meter should be set lower than 0.5V and then align F621 until the indication of voltage meter is at 0V.

(B) FM RF board alignment

- (a) Connect FM RF S.G. to the antenna of the receiver through dummy antenna, and AC V.T.V.M. to the speaker output of either channel.
- (b) Set the output level of FM RF signal generator to $3\mu\text{V}$, and modulation to 1kHz deviation (30%). Adjust VOL of the receiver to the adequate position in accordance with indication of AC V.T.V.M.

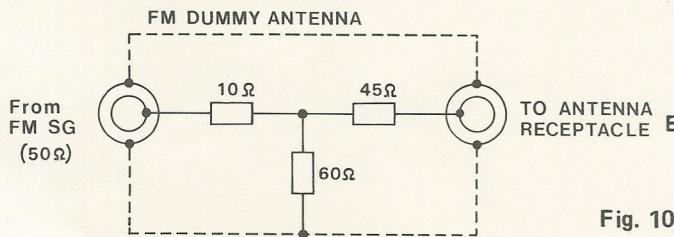

Fig. 10

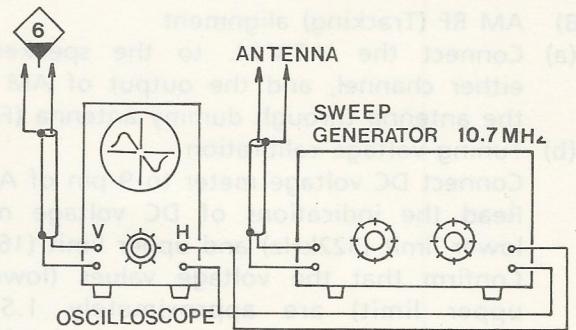

Fig. 6

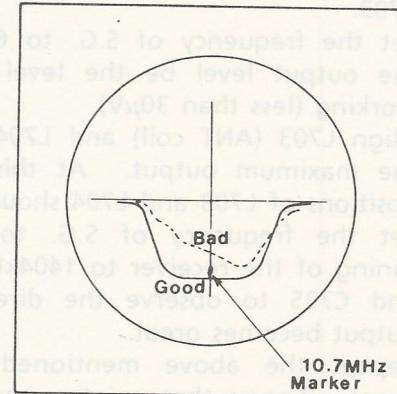

Fig. 7

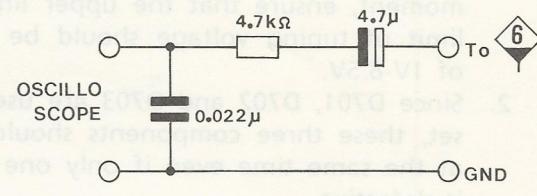

Fig. 8

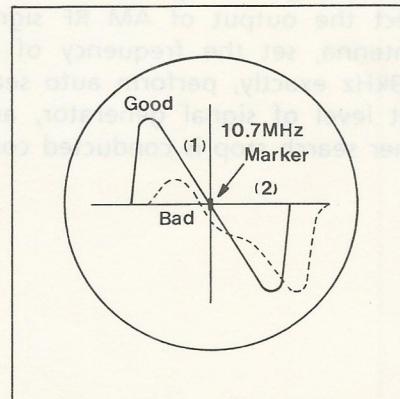

Fig. 9

(c) Tuning voltage calibration

Connect DC voltage meter to terminal No.4 of FM RF. Set the tuning of the receiver to 87.5MHz. Record the reading of DC voltage meter, then change the tuning of the receiver to 108.0MHz and in turn record the reading of DC voltage meter. Confirm that the two voltage values are to be approximately 1.5V and 7V, respectively. If the values indicated are greatly deviated from the standard ones, adjust L605 and C617.

Note: Since 1.2V and 9V are the allowable extreme values, reconfirmation must be made should L605 or C617 be moved for further alignment.

- (d) Tune the frequency of FM RF signal generator to 88.1MHz exactly, and the tuning of the receiver to 88.1MHz as well. Align L601 (Antenna coil) and L603 (RF coil) to obtain the maximum indication of the V.T.V.M.

- (e) Tune the frequency of FM RF signal generator to 107.9MHz, and the tuning of the receiver to 107.9MHz as well. Move L601 and L603 to observe the reading of the V.T.V.M. If the indication of the V.T.V.M. increases when the density of coils winding decreases (becomes coarse), replace C603 and C610 with other capacitors having smaller capacity, and then perform the alignment of procedure (d). To the contrary, when the density of coils winding increases (becomes dense), replace C603 and C610 with other capacitors having larger capacity.

- (f) Repeat the alignment of procedure (d) and (e) to obtain the maximum indication of the V.T.V.M.

Note: Since C603, C610 and C617 are chip capacitors, soldering iron used in soldering should be less than 30W, and the temperature of the iron tip should be less than 280°C. Do not touch ceramic part directly with iron tip when performing operation.

Note:

1. If the change of indication of the V.T.V.M. is only a bit when moving L601 and L603 for adjustment, adjust L605 at 88.1MHz to obtain maximum sensitivity.
2. The characteristics of D601, D602 and D603 are similar so that the three components should be replaced at the same time even if only one of the three is defective or damaged. Otherwise, the specified performance may not be obtained even the above mentioned adjustments are performed repeatedly.
3. Whenever (B) FM RF board alignment is done, it must be followed by (A) FM IF alignment.

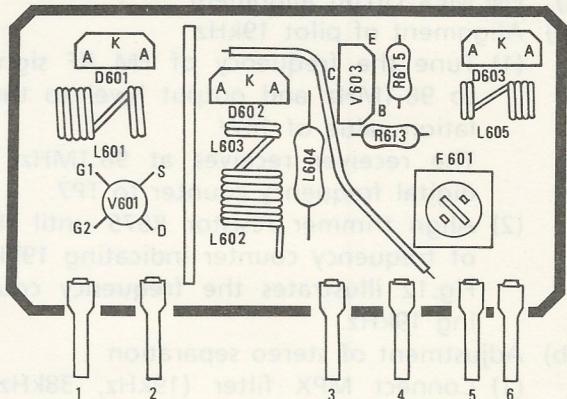

Fig. 11

(C) FM MPX circuit alignment

(a) Alignment of pilot 19kHz

- (1) Tune the frequency of FM RF signal generator to 98.1MHz and output level to the not modulation value of 1mV.

The receiver receives at 98.1MHz. Connect a digital frequency counter to TP7.

- (2) Align trimmer resistor R675 until the indication of frequency counter indicating 19kHz. Refer to Fig.12 illustrates the frequency counter indicating 19kHz.

(b) Adjustment of stereo separation

- (1) Connect MPX filter (19kHz, 38kHz Null filter) between the speaker output and AC V.T.V.M.

Set the output level of FM RF signal generator to 1mV, and set the modulator to 75kHz deviation (10% for pilot signal and 90% for 1kHz main signal L + R).

- (2) Tune the mode selector of the stereo modulator to the R channel. Align trimmer resistor R667 to obtain maximum separation.

In case L channel is selected by the mode selector, also perform the adjustment similarly. If the trimmer resistor R667 of the mode selector is set in different position for R and L channels, align it so that equal separation can be obtained on both channels.

DOLBY NR CIRCUIT

Equipment required

1. Stabilized power supply (DC 14V)
2. AC V.T.V.M.
3. Dolby NR level calibration tape (TEAC MTT-150 or equivalent)

(A) Dolby NR tape level adjustment

(a) Play back Dolby NR level calibration tape.

- (b) Set Dolby NR switch H62 to "OFF" position and adjust the trimmer resistor R110 (L ch) and R210 (R ch) for tape level adjustment in order to obtain 650mV of reading on V.T.V.M. at the test point of TP9 (L ch) and TP10 (R ch).

- (c) The difference of the level between Forward and Reverse directions of the tape transport/reproduction should be ± 1 dB. (Refer to Fig. 13.)
