

for 100 Watt P.A. Amplifier

AWA Models PA1001AZ and PA1001BZ.

These models are high performance vacuum tube amplifiers delivering 100 watts.

Model PA1001AZ is designed for booster applications while Model PA1001BZ is designed for system applications.

A feature of these amplifiers is a driver/output stage of unique design developed by AWA which enables the output valves to be operated in Class AB1 without loss of performance since the coupling between all sections of the output transformer primary is maintained at 100% at all frequencies. Long valve life is thus ensured as the output stage only reaches full current on signal peaks. As a further aid to reliability, cathode resistors in all stages provide consistency of operation and overload protection.

OPERATIONAL LAYOUT.

The general disposition of controls is as follows:-  
Operation controls are on the front panel, input terminals are on the left hand side and output terminals, pre-set controls and test points are at the rear.

All controls are clearly marked and their operation is quite conventional.

PRE-SET ADJUSTMENTS.

To provide reliability and protection to the amplifier the following adjustments are provided. These adjustments have been accurately made at the factory but may need to be repeated during the life of the equipment.

BIAS ADJUSTMENT of V4, V5, V6 and V7.

These adjustments are to be carried out whenever 7027A valves are replaced.

V4 and V5 Bias.

Adjust with no signal input into the amplifier.

Connect a d.c. voltmeter between the rear test points V4 and E. Adjust the V4, V5 BIAS control to give 8 volts. Move the meter to V5 test point and check it for 8 Volts, adjusting the control if necessary to compromise for V4 and V5 variations.

V6 and V7 Bias.

Connect the meter between test points V6 and E.

Adjust the V6, V7 BIAS control to give 8 volts. Move the meter to V7 test point and check it for 8 volts, adjusting the control if necessary to compromise for V6 and V7 variations.

N.B. Repeat the above adjustments for these two controls several times to obtain the closest balance possible. In some cases it may be necessary to swap valves around to have the closest

matching pairs in parallel.

#### A.C. BALANCE.

Several methods may be used depending on the test equipment available.

##### Method 1.

Connect a resistive load across the OUTPUT terminals with the shorting links correctly connected, e.g. joining 3-4, 6-7, 9-10 and use a 100 ohm load.

Connect a Distortion and Noise meter across part of the resistive load and apply an input signal of 1000 Hz to give almost full output from the amplifier, e.g. 90 volts across the 100 ohms load.

Adjust the A.C. BAL control for minimum total harmonic distortion.

##### Method 2.

Connect a resistive load on the amplifier as above.

Connect an oscilloscope across the 3.3 ohm resistor (R58) and apply a 1000 Hz input signal.

At an output of approximately 10% of full output, e.g. 10 volts across 100 ohm load, adjust the A.C. BAL. control for the minimum amplitude of the high frequency component of the c.r.o. signal.

##### Method 3.

A simplified version of method 2 above can be achieved by feeding the output of a radio into the amplifier and, with earphones connected across R58 (3.3 ohms), adjusting the A.C. BAL. control for minimum noise on the radio program.

#### OUTPUT LIMITER.

Turn the control fully anti-clockwise.

Connect a resistive load across the OUTPUT terminals with the shorting links correctly connected e.g. join 3-4, 6-7, 9-10 and use a 100 ohm load.

Apply a 1000 Hz signal to the amplifier and increase the signal level until the amplifier gives full output i.e. 100 volts across a 100 ohm load. Turn the OUTPUT LIMITER control until the limiter circuit just commences to work. This will be seen as a "blinking" on a voltmeter or an oscilloscope.

A similar adjustment may be used to set the limiter at levels below 100 watts. e.g. 75 watts-87 volts in 100 ohm load

50 watts-70 volts in 100 ohm load.

N.B. If no facilities are available for setting the limiter no damage will be done to the amplifier if the OUTPUT LIMITER control is left in its fully anti-clockwise position.

Model PA1001A.

Power Output: 100 watts (continuous sine wave at 1,000 Hz)

Distortion : less than 3% at 100 watts at 1,000 Hz

Sensitivity.

Input 1 : Pin 1 - E: 300mV

Input 2 : Pin 4 - E: 300mV

Hum/Noise : -65db.

Tone Control : Bass Cut Switch -5db at 200 Hz

Response : 3db points 50-12,000 Hz.

Regulation : better than 2db.

Model PA1001BZ.

Power Output: 100 watts (continuous sine wave at 1,000 Hz)

Distortion : less than 3% at 100 watts at 1,000 Hz

Sensitivity.

Mic. (High Imp) : 3mV

Phono : 200mV

Hum/Noise

Mic. : -45db

Phono : -55db.

Tone Control.

Phono/Radio Tone Control: - 5db at 2,000 Hz

Bass Cut Switch : - 5db at 200 Hz

Response : 3db points 50-12,000 Hz.

Regulation : better than 2db.
